Abstract: *Phytoseiid mites are known as the important predators of phytophage mites and small insects. These mites are found in various crops. A faunistic and dispersion survey of phytoseiid mites was carried out from 2010-2013 in more than 10 province orchards, selected from all the western regions of Iran. Different samples were taken from soil, trees, crops and weeds. After clearing the mites in lactophenol fluid, the slides were made and then identified. In this research 23 species from 7 genera of the family phytoseiidae were collected in the western of Iran. 28% of recorded mites were found in Markazi province and the most mites recorded were collected in soil. The highest mite numbers were observed in the altitude range (1500-2000 m). Subfamily Typlodrominae were found at lower temperature than the subfamily Amblyseiinae. The phytoseiid mites were found in region with the mean temperature range (12-20°C) and the mean humidity range (34-50%).*

Keywords: Phytoseiid mites, province, record, temperature, humidity.

1. Introduction

Mites of the family Phytoseiidae are the most common predators of phytophagous mites on most plant species. Some species are widely studied and used for biological control of mite pests [1]. Many new species continue to be discovered as collection are intensified in certain regions or habitats e.g. in Africa, Asia, Central and South America. Moraes catalog includes almost 2250 species [2]. The widespread interest in the Phytoseiidae Berlese (Acari: Mesostigmata) as biological control agents of Phytophagous mites and thrips is evident from the more than 4000 publication on phytoseiid from 1690-1996 [3]. More than 70 species have been reported as new species or new records for Iran [4]-[32] (Table 1).

Some researchers investigated the distribution of phytoseiid mite in different regions e.g. [33]-[35]. Some researchers investigated about the effect of temperature on distribution of phytoseiid mites [36].

During 2010-2012, in a dispersion survey of phytoseiid mites in 10 provinces, different samples were taken from soil, trees, crops and weeds. The effect of temperature and humidity were studied in this study.

Table 1. the phytoseiid mites were recorded in different regions of Iran.

2. Material:

The mites were collected from 10 provinces of Iran (Markazi, Hamedan, Lorestan, Kermansha, Elam, Semnan, Tehran, Alborz, Ghazvin and Qoam). The specimens were taken during spring and summer 2010-2012. The mites were collected by placing plant foliage, litter and soil in a Berlese or by direct examination under a stereomicroscope. Mites were cleaned in lacto phenol solution and mounted in Hoyer's medium on microscope slides. The notations used for dorsal and ventral setations follow those of Rowell *et al.*, 1978 and Chant & Yoshida-Shaul (1992)[37], [38].

Longitude, latitude and altitude were saved during was measured with the hand GPG signal receiver (device GPS Map 60CS). Temperature and humidity were recorded at site.

3. Result and Dissociation

We collected the phytoseiid mites of three subfamilies Amblyseiinae, Phytoseiinae and Typhlodrominae. Four tribes *Neoseiuliini*, *Amblyseiini*, *Kampimodromiini*, *Euseiini* were recorded for subfamily Amblyseiinae. Seven species were recorded for *Neoseiuliini*, two species for *Amblyseiini*, a species for *Kampimodromiini*, two species for *Euseiini*. We found a species for subfamily Phytoseiinae. We recorded two tribes, tribe *Paraseiuliini* (3 species) and tribe *Typhlodromiini* with eight species in this study (Table 2).

On the base of other studies the highest number of phytoseiid mites recorded at Mazandaran province (20%) and the other provinces the phytoseiid mites numbers were recorded as Gilan

provine (15%), Tehran (8%), the south provinces (9%), Azarbajan (11%), Kermanshhe (3%), Khorsan (4%), Zanjan (15%), Charmahal (6%), Lorestan (1%), Hamedan (3%), Markezi (2%), Kerman (2%). In this study, the most mite numbers recorded in Markazi provine (28%), Albroz provine (20%), Lorestan provine (20%), Seman provine (11%), Kermansha (11%). The use of pesticides, applied several times during the year before sampling, explains the absence of phytoseiid mites in some regions [39].

Among the host plants, the most number recorded on apple leaves (11%), citrus leaves (10%) and in soil (13%), and on the host record as cotton (1%), rice (1%), fig (7%), oak (4%), pomegranate (4%), berry (4%), walnut (3%). 41% of phytoseiid mites recorded in soil, other host plants recorded as (14%) on pomegranate, 14% on apple, 8% on rose and 8% on grapes. Phytoseiid species showed different development, reproduction and efficiency according to roughness and hairiness of plant leaves. Some phytoseiid species developed faster on smooth, glabrous leaves than or rough, hairy ones [40]. In other studies such as, Duso & Pellegrini (2003) investigated the effect of apple cultivars on the distribution of the predatory mite, that large phytoseiid population were recorded on the apple cultivar, despite the low eriophyid occurrence, probably because of its highly pubescent leaf undersurfaces.

Pilesjö *et al* (2005) featured that different topographical parameters can be used to delineate agricultural management zones [41]. Soil characteristics play an important role in crop growth and yield. Soil properties vary with topographic settings. Topographical data in combination with soil information are useful for explaining yield variability on an agricultural field scale [42].

The highest mite number (52%) were observed in higher altitude (1500-2000 m) and 7% were recorded in <2000 m and 13% of phytoseiid mites were observed in lower altitude (<1000 m) and the other mites in this study (26%) were collected in altitude range (1000-1500 m).

The mean temperature that subfamily Amblyseiinae were recorded 16.4 °C and the humidity was 41.6 % however the temperature that the other subfamily (Typhlodrominae) were collected was lower (13.8 °C). The phytoseiid mites of subfamily Typhlodrominae need the lower temperature than subfamily Amblyseiinae.

The mean temperature that four tribes of Amblyseiinae were recorded as *Neosiuilini* (16.2°C), *Amblyseiini* (17.4°C), *Kampinodromiini* (17.4°C), *Euseiini* (17.4°C) and the mean humidity were recorded 42%, 42%, 41.5%, 41.5% respectively.

The mean temperature and humidity were recorded for two tribes of subfamily Typhlodrominae as follow *paraseiuliini* (13.5°C), 47% and *Typhlodromiini* 12.3°C , 46.5%. The phytoseiid mites were found in region with the mean temperature range ($12\text{-}20^{\circ}\text{C}$) and the mean humidity range (34-50%).

The geographic distribution of the four species in the genus *Phytoseiulus* was surveyed. This genus is known only from tropical and subtropical areas. All four species have been recorded from south America, but none from Asia, *Phytoseiulus macropilis*, the most widely distributed species in the genus, is known from the west coast of Africa to some islands in the southwestern Pacific Ocean. *Phytoseiulus persimilis* is known mainly from Mediterranean climate [43]. In this study the mean temperature and humidity were recorded for this species was 16.8°C and 36% respectively.

More than 1982 species in 90 genera was included in an analysis of the biogeography of the phytoseiidae. Seven biogeographic regions were taken into account: Nearctic, Neotropical, Ethipian, west Palaearctic, East Palaearctic, Oriental, Australasian. The number of species was particularly high in the neotropical, oriental and west Palaearctic regions. These regions also present the highest level of species endemism. The number of genera was quite similar in all regions except for Neotropics, which also a high level of endemism [44].

Chant (2009) [45] reported twenty- three species in 4 genera (*Neseiulus* Hunges, *Amblyseius* Berlese, *Chelaseius* Muma & Demark and *Proprioseiopsis* Muma from northern tundra, in Alaska, Canada, Greenland Iceland, Russia & Norway. In another study, no significant relationships were found between total acari dispersal and any weather variables [46].
